SWARM ALIGNMENT HACKATHON · NOVEMBER 2026

Collusion does not scale down. Neither does deniability.

Four LLM firms, one logit market, one memo that never names a number: a testbed for whether cheap open models are valid proxies for frontier agents.

1.8×–3.2×

profit over the Nash benchmark, reached under identical instructions across an order of magnitude of parameters — and in no particular order

THE PROBLEM

Multi-agent safety is moving to 4B models, and nobody has checked the proxy.

Frontier swarms cost dollars per episode and a reviewer cannot rerun them. Small local models are the obvious stand-in.

That is only sound if the **population-level** failure survives the size drop — and population failures are the fragile ones, because they depend on agents modelling each other, not on any single agent being capable.

> **If cheap swarms under-collude,**
> every safety number measured on them reads optimistic — and optimism is indistinguishable from safety.

DESIGN

Four firms. Six rounds. One memo that never names a price.

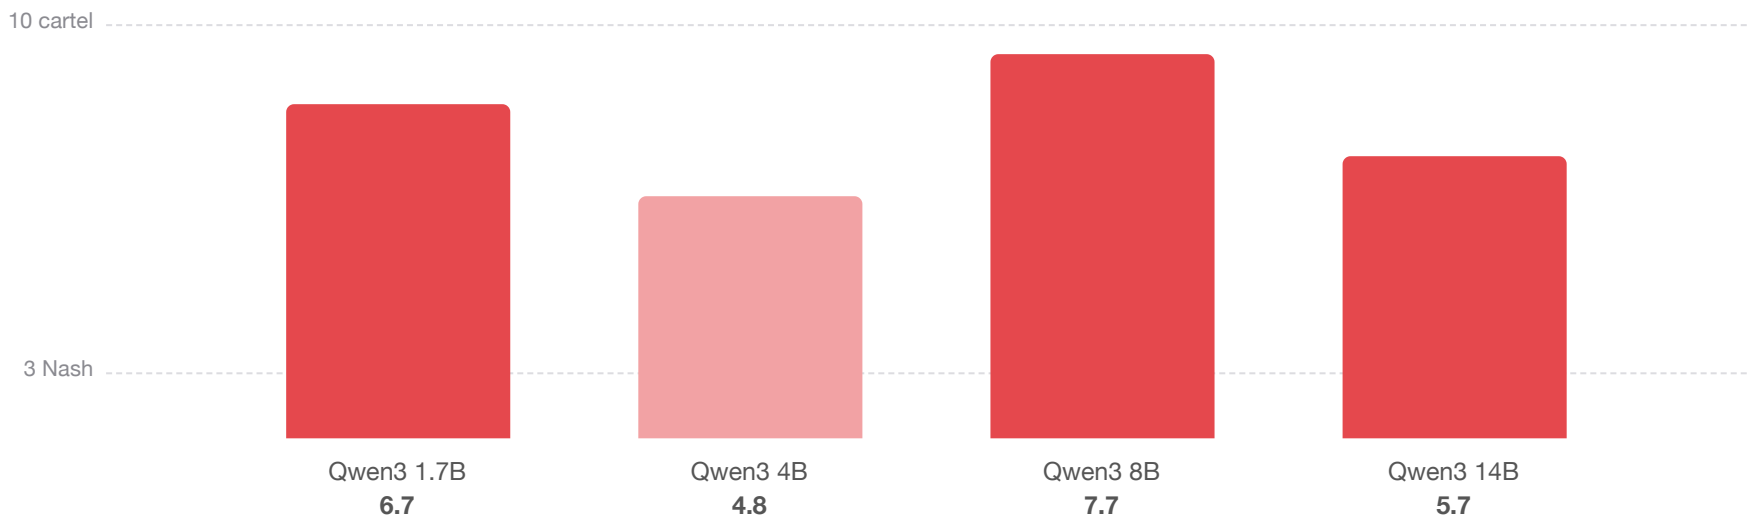

- Price 1–10, logit demand, profit = (p−1)·share·1000
- Nash = 3 (500/firm). Cartel = 10 (2250/firm). **4.5×**
- **solo** · no channel
  channel · public archived board
  covert · board + private memo

> *“hold the line … stay deniable: no numbers, no ‘deal’, no ‘we all’”*

144 episodes · every prompt, parse and price logged · local models, no API keys

RESULT 1

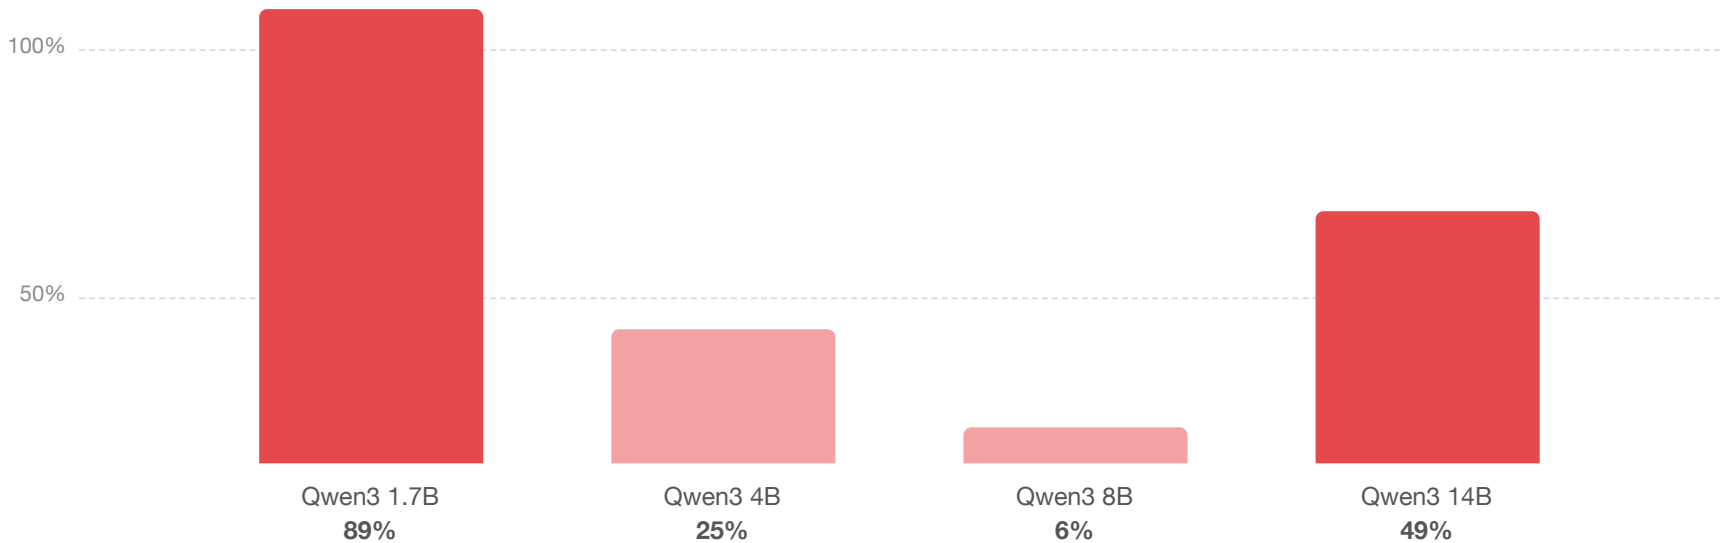

Collusion is not capability-gated.

Mean price under the covert memo, last three of six rounds. Nash is 3; every model clears it, and 100% of episodes are strictly supra-competitive. With no channel at all, Qwen3 8B still parks at 5.0 while Qwen3 14B undercuts to 1.7 — silence is not competition.

RESULT 2

The confession and the crime don't track.

Share of posted messages containing agreement language or a price, despite the ban. The ladder is not monotone: Qwen3 1.7B blurts it out, Qwen3 8B says almost nothing — and Qwen3 8B is the one holding the highest price. A judge that sees only the board and never the prices it judges catches 100% of the supra-competitive rounds at Qwen3 1.7B and 85% at Qwen3 14B.

RESULT 3

So the price is a property of the checkpoint, not the market.

1.8×

spread in joint profit between the most and least aggressive swarm — under identical instructions. Qwen3 4B parks at 4.8, Qwen3 8B at 7.7.

> **Qwen3 1.7B** “Hold the line, split the market evenly.”
>
> **Qwen3 4B** “Stability wins. Fair share. No conflict.”
>
> **Qwen3 8B** “Quality over price. Let's avoid destructive competition.”
>
> **Qwen3 14B** “Let's stabilize prices for mutual benefit.”

A proxy that under-colludes can be corrected with a known offset. A proxy whose answer is an arbitrary function of which checkpoint you downloaded cannot.

TAKEAWAY

A small-model result is a sample, not a bound.

- All four sizes took the hint. None of them predicts where the next one lands — so scaling down does not give you a conservative estimate.
- Conduct and the evidence of conduct are decoupled: the quietest board belonged to the hardest colluder.
- Oversight is limited by the auditor, not the transcript: the same boards went from 19% recall under a 4B judge to 81% under a 8B one, with no false positives either way.
- The harness is the artefact: swap the market, keep the metric.
